## Chapter 12 - Equilibrium and Elasticity

I. Equilibrium

- Definition
- Requirements
- Static equilibrium
II. Center of gravity
III. Elasticity
- Tension and compression
- Shearing
- Hydraulic stress

## I. Equilibrium

- Definition: An object is in equilibrium if:
- The linear momentum of its center of mass is constant.
- Its angular momentum about its center of mass is constant.

Example: block resting on a table, hockey puck sliding across a frictionless surface with constant velocity, the rotating blades of a ceiling fan, the wheel of a bike traveling across a straight path at constant speed.

- Static equilibrium:

$$
\begin{array}{lll}
\vec{P}=0, & \vec{L}=0 & \begin{array}{l}
\text { Objects that are not moving either in } \\
\text { TRANSLATION or ROTATION }
\end{array}
\end{array}
$$

Example: block resting on a table.

## Stable static equilibrium:

If a body returns to a state of static equilibrium after having been displaced from it by a force $\rightarrow$ marble at the bottom of a spherical bowl.

## Unstable static equilibrium:

A small force can displace the body and end the equilibrium.

(1) Torque about supporting edge by $F_{g}$ is 0 because line of action of $F_{g}$ passes through rotation axis $\rightarrow$ domino in equilibrium.
(2) Slight force ends equilibrium $\rightarrow$ line of action of $F_{g}$ moves to one side of supporting edge $\rightarrow$ torque due to $F_{g}$ increases domino rotation.
(3) Not as unstable as (1) $\rightarrow$ in order to topple it, one needs to rotate it beyond balance position in (1).

- Requirements of equilibrium:
$\vec{P}=$ cte $\rightarrow \vec{F}_{n e t}=\frac{d \vec{P}}{d t}=0 \quad$ Balance of forces $\rightarrow$ translational equilibrium
$\vec{L}=$ cte,$\quad \vec{\tau}_{n e t}=\frac{d \vec{L}}{d t}=0 \quad$ Balance of torques $\rightarrow$ rotational equilibrium
- Vector sum of all external forces that act on body must be zero.
- Vector sum of all external torques that act on the body, measured about any possible point must be zero.

Balance of forces $\rightarrow \mathrm{F}_{\text {net,x }}=\mathrm{F}_{\text {net,y }}=\mathrm{F}_{\text {net, } \mathrm{z}}=0$

Balance of torques $\rightarrow \tau_{\text {net }, \mathrm{x}}=\tau_{\text {net, } y}=\tau_{\text {net }, \mathrm{z}}=0$

## II. Center of gravity

Gravitational force on extended body $\rightarrow$ vector sum of the gravitational forces acting on the individual body's elements (atoms)
$\boldsymbol{\operatorname { c o g }}=$ Body's point where the gravitational force "effectively" acts.

This course initial assumption: The center of gravity is at the center of mass.

If $g$ is the same for all elements of a body, then the body's Center Of Gravity (COG) is coincident with the body's Center Of Mass (COM).

Assumption valid for every day objects $\rightarrow$ " $g$ " varies only slightly along Earth's surface and decreases in magnitude slightly with altitude.

## Proof:

$$
\begin{aligned}
& x_{\operatorname{cog}} \sum_{i} F_{g i}=\sum_{i} x_{i} F_{g i} \rightarrow x_{\operatorname{cog}} \sum_{i} m_{i} g_{i}=\sum_{i} x_{i} m_{i} g_{i} \rightarrow x_{\operatorname{cog}} \sum_{i} m_{i}=\sum_{i} x_{i} m_{i} \\
& \rightarrow x_{\text {cog }}=\frac{1}{M} \sum_{i} x_{i} m_{i}=x_{c o m}
\end{aligned}
$$

of mass about the origin O , with moment arm $\mathrm{x}_{\mathrm{i}}$.

$$
\tau=r_{\perp} F \rightarrow \tau_{i}=x_{i} F_{g i} \rightarrow \tau_{\text {net }}=\sum_{i} \tau_{i}=\sum_{i} x_{i} F_{g i}
$$

$$
\tau=x_{\operatorname{cog}} F_{g}=x_{\operatorname{cog}} \sum_{i} F_{g i}=\tau_{n e t}
$$

## III. Elasticity

Branch of physics that describes how real bodies deform when forces are applied to them.

Real rigid bodies are elastic $\rightarrow$ we can slightly change their dimensions by pulling, pushing, twisting or compressing them.

Stress: Deforming force per unit area.
Strain: Unit deformation

Shearing stress

Hydraulic stress

Tensile stress: associated
with stretching

Elastic modulus: describes the elastic behavior (deformations) of objects as they respond to forces that act on them.

Stress = Elasticity Modulus x Strain

(1) Stress $=$ cte $\times$ Strain $\rightarrow$ Recovers original dimensions when stress removed.
(2) Stress $>$ yield strength $S_{y} \rightarrow$ specimen becomes permanently deformed.
(3) Stress $>$ ultimate strength $\mathrm{S}_{\mathrm{u}} \rightarrow$ specimen breaks.

Tension and compression:
Stress $=\frac{F}{A}$
( $F=$ force applied perpendicular to the area $A$ of the object)

Strain $=\frac{\Delta L}{L} \quad$ ( fractional change in length of the specimen)
Stress $=$ (Young's modulus) $\times$ Strain

$$
\frac{F}{A}=E \frac{\Delta L}{L}
$$

Units of Young modulus: F/m²
Shearing:

$$
\begin{array}{ll}
\text { Stress }=\frac{F}{A} & \begin{array}{l}
\text { ( F = force in the plane of the } \frac{F}{A}=G \frac{\Delta x}{L} \\
\text { area A) }
\end{array} \\
\text { Strain }=\frac{\Delta x}{L} & \text { ( fractional change in length of the specimen) }
\end{array}
$$

Stress = (Shear modulus) x Strain

Hydraulic stress:

$$
\text { Stress }=\text { Fluid pressure }=p=\frac{F}{A} \quad p=B \frac{\Delta V}{V}
$$

Hydraulic Stress = (Bulk modulus) x Hydraulic compression

$$
\text { Strain }=\frac{\Delta V}{V}
$$
