(Received 28 January 2009; accepted 23 March 2009; published online 21 April 2009)

We present a method of self-assembly of densely packed and aligned bilayer ZnO nanorod arrays in a hydrothermal synthesis process. The alkali hydrothermal environment first induced the growth of hydrotalcitelike zincowoodwardite plates, which provide a lattice-matched surface for the self-assembly of ZnO nanorod arrays. The high packing density of the ZnO nanorod arrays demonstrates efficient nucleation and growth processes of ZnO on the zincowoodwardite. The interfacial phenomena involved in the growth of ZnO and self-assembly are discussed. The two-dimensional arrays of ZnO nanorods may find future applications in nanoelectronics and nanophotonics. © 2009 American Institute of Physics. [DOI: 10.1063/1.3118583]

Self-assembly of nanostructured building blocks into large ordered hierarchical heterostructures is important for bottom-up strategies in near-future nanotechnology applications.¹,³ Various self-assembled hierarchical heterostructures have been reported before.¹ The importance of one-dimensional ZnO nanorods has been recognized due to its excellent materials properties. The capability to synthesize large quantities of uniform ZnO nanorods has been reported by different groups.⁷–¹¹ Our work¹²–¹⁴ demonstrated a fast, simple, and safe hydrothermal method for the growth of one-dimensional ZnO nanorods has been recognized due to large ordered hierarchical heterostructures is important for self-assembly of densely packed and aligned ZnO nanorod arrays. In this process, ultrathin hydrotalcitelike zincowoodwardite [Zn₁₋ₓAlₓ(OH)₂·2CO₃·nH₂O].¹⁵ Liu et al.¹⁶ described the synthesis of ZnO/Zn-Al layered double hydroxide (LDH) hierarchical heterostructures using an Al substrate suspended in a Zn(CH₃CO₂)₂ aqueous solution. Koh and Loh¹⁷ used aluminum-coated silicon as a substrate to synthesize hydrotalcitelike Zn–Al LDH in zinc acetate and ammonia water to grow self-assembled ZnO nanorods on Zn–Al LDH.

Here, we report a template-free solution growth self-assembly technique to synthesize bilayers of densely packed and aligned ZnO nanorod arrays. In this process, ultrathin hydrotalcitelike zincowoodwardite, [Zn₁₋ₓAlₓ(OH)₂·SO₄] plates are first synthesized in the solution. The alignment of the self-assembled bilayer ZnO nanorods is a direct consequence of the heterogeneous epitaxial growth of ZnO [0001] nanorods on the zincowoodwardite plates.

In the synthesis process, 100 ml of 0.1–0.5 M zinc sulfate [Zn(SO₄)₂·7H₂O] was mixed with 100 ml of 0.001–0.005 M of aluminum sulfate [Al₂(SO₄)₃·18H₂O] first. Then sodium hydroxide (2 M) was gradually added until the mixture solution become colorless/transparent. This aqueous complex solution was heated to a temperature of 85–95 °C for 15 min without any stirring. Then the heater was turned off and the solution was allowed to cool to room temperature. The synthesized materials on the silicon substrate were removed from the solution, then were washed with de-ionized water and dried in a hot-air flux.

Zincowoodwardites are layered compounds with positively charged layers of Zn²⁺ and Al³⁺. These compounds have been studied²⁰ as catalysts, anionic exchanges, and sorbents. When the supply of Al³⁺ ions is unlimited, the zincowoodwardite will continue to grow and form interpenetrating plates, as shown in Fig. 1(a). However, if the supply of Al³⁺ ions is limited, as Al³⁺ ions were consumed, the growth of zincowoodwardite flakes will stop and the ZnO nanorods will start to grow on the basal plane of zincowoodwardite, since the lattice spacing in the ZnO basal plane matches quite well with the lattice spacing in the zincowoodwardite basal plane.

A FEI 200 focused ion beam (FIB) system was used to prepare samples for transmission electron microscope (TEM) experiments from the freestanding ZnO nanorod assembly. The ZnO self-assembly sample was mounted on a copper grid. The TEM experiment was performed with a FEI F30 TEM operating at 300 kV. Raman spectra were obtained using an excitation source with 633 nm radiation from a helium neon laser. The laser power was varied from 0.5 to 4 mW. All Raman spectra were acquired at room temperature.

Figure 1(a) shows flakes of zincowoodwardite, which were produced when the Al³⁺ ions concentration is high in the mixture solution. Figure 1(b) shows a typical bilayer of densely packed and aligned ZnO nanorod arrays in a template-free solution growth technique. The ZnO nanorods are aligned with each other quite well and perpendicular to the zincowoodwardite middle layer, which is too thin to be visible at this magnification. The high packing density of the aligned ZnO nanorods demonstrates efficient nucleation and growth processes of ZnO on the zincowoodwardite, as both sides of the plate can act as nucleation sites for the aligned ZnO nanorods arrays.

Furthermore, the nanorods in the array all have similar diameters and lengths, as shown in Fig. 1(b). Each individual ZnO nanorod has an average radius of 50 nm and the length...
of the nanorod is about 700 nm. In Fig. 1, multiple bilayer structures of ZnO nanorod bundles are shown. The controlled growth of individual, transferable units of the ZnO nanorod arrays on the \( \text{Zn}_{1-x}\text{Al}_x\text{OH}_2 \cdot \text{SO}_4 \) plate, as shown in Figs. 1(b) and 1(c), may be used as a freestanding, lasing array with highly oriented ZnO nanorods. Such densely packed and aligned arrays could also be used as potential photonic waveguide structures.

In order to investigate the growth mechanism of this self-assembled ZnO nanorod bilayer, TEM, and focused ion beam (FIB) are employed. The FIB technique has been used to fabricate ZnO nanorod devices by us in the past. Here, FIB is employed to prepare a cross-sectional TEM sample. In Fig. 2, a TEM micrograph shows the zincowoodwardite plate sandwiched between two ZnO nanorod layers. The ultrathin zincowoodwardite plate has a thickness of about 60 nm. Some charging effect is seen on the zincowoodwardite plate indicating that it has a lower conductivity than the ZnO nanorods. The inset at the top left corner shows the EDX spectrum of the zincowoodwardite layer. We can see that Zn, Al, O, and S peaks are clearly present. The Cu K\( \alpha \) peak at 8 keV originates from the TEM Cu grid on which the sample was mounted. The inset at the

of the nanorod is about 700 nm. In Fig. 1(c), multiple bilayer structures of ZnO nanorod bundles are shown.

The controlled growth of individual, transferable units of the ZnO nanorod arrays on the \( \text{Zn}_{1-x}\text{Al}_x\text{OH}_2 \cdot \text{SO}_4 \) plate, as shown in Figs. 1(b) and 1(c), may be used as a freestanding, lasing array with highly oriented ZnO nanorods. Such densely packed and aligned arrays could also be used as potential photonic waveguide structures.

In order to investigate the growth mechanism of this self-assembled ZnO nanorod bilayer, TEM, and focused ion beam (FIB) are employed. The FIB technique has been used to fabricate ZnO nanorod devices by us in the past. Here, FIB is employed to prepare a cross-sectional TEM sample. In Fig. 2, a TEM micrograph shows the zincowoodwardite plate sandwiched between two ZnO nanorod layers. The ultrathin zincowoodwardite plate has a thickness of about 60 nm. Some charging effect is seen on the zincowoodwardite plate indicating that it has a lower conductivity than the ZnO nanorods. The inset at the top left corner shows the EDX spectrum of the zincowoodwardite layer. We can see that Zn, Al, O, and S peaks are clearly present. The Cu K\( \alpha \) peak at 8 keV originates from the TEM Cu grid on which the sample was mounted. The inset at the

of the nanorod is about 700 nm. In Fig. 1(c), multiple bilayer structures of ZnO nanorod bundles are shown.

The controlled growth of individual, transferable units of the ZnO nanorod arrays on the \( \text{Zn}_{1-x}\text{Al}_x\text{OH}_2 \cdot \text{SO}_4 \) plate, as shown in Figs. 1(b) and 1(c), may be used as a freestanding, lasing array with highly oriented ZnO nanorods. Such densely packed and aligned arrays could also be used as potential photonic waveguide structures.

In order to investigate the growth mechanism of this self-assembled ZnO nanorod bilayer, TEM, and focused ion beam (FIB) are employed. The FIB technique has been used to fabricate ZnO nanorod devices by us in the past. Here, FIB is employed to prepare a cross-sectional TEM sample. In Fig. 2, a TEM micrograph shows the zincowoodwardite plate sandwiched between two ZnO nanorod layers. The ultrathin zincowoodwardite plate has a thickness of about 60 nm. Some charging effect is seen on the zincowoodwardite plate indicating that it has a lower conductivity than the ZnO nanorods. The inset at the top left corner shows the EDX spectrum of the zincowoodwardite layer. We can see that Zn, Al, O, and S peaks are clearly present. The Cu K\( \alpha \) peak at 8 keV originates from the TEM Cu grid on which the sample was mounted. The inset at the
lower right corner shows the EDX spectrum of the ZnO nanorods. It is clear that only Zn and O peaks are present. From Fig. 2, we can conclude that the densely packed ZnO nanorods grow perpendicular to the zincowoodwardite basal plane. Zincowoodwardite belongs to a family of layered compounds \(^{18-20}\) with positively charged layers of Zn\(^{2+}\) and Al\(^{3+}\), and interlayered charge balancing anions (SO\(_4\))\(^{2-}\). It has a lattice constant of 3.076 Å in the basal plane which matches with the lattice constant of [0001] plane of the hexagonal ZnO crystal (3.249 Å) to within 5%. This provides a plane for the growth of ZnO [0001] nanorods.

In Fig. 3(a), the small-area electron diffraction (SAED) patterns reveal a hexagonal symmetry when the electron beam aligned parallel to the ZnO nanorod c-axis. The electron beam is spread over several nanorods, the diffraction pattern reveals not only the crystal structure and lattice parameters, but also orientation relations between these nanorods. It shows that (2,1,−3,0) diffraction spots from neighboring nanorods overlap, while {0,1,−1,0} and {1,1,−2,0} reflections from different nanorods are rotated with respect to each other. This corresponds to \(\Sigma 7\) grain boundaries and rotations of 38.21° about the c-axis for crystal lattices in neighboring nanorods. The inset at the lower right corner shows a simulated diffraction spots for a diffraction pattern along [0001] with two crystallographic domains rotated by 38.21°. In Fig. 3(b) a high-resolution TEM image of the ZnO nanorods reveals that they are high-quality single crystals without defects. The inset in Fig. 3(b) shows the SAED image from one individual nanorod along [0001] direction.

To demonstrate the optical quality of these densely packed ZnO arrays, we carried out Raman measurements using a He–Ne laser. Figure 4 shows Raman spectrum of ZnO nanorod arrays. It can be seen that the dominant peaks at 100 cm\(^{-1}\) and 438 cm\(^{-1}\) are attributed to the low- and high-E\(_2\) mode of nonpolar optical phonons, \(^{24}\) respectively. The E\(_2\) mode \(^{25}\) has a width of 11 cm\(^{-1}\), indicating a good crystal quality of the self-assembled ZnO nanorod-bundle structures. The peak at 335 cm\(^{-1}\) is attributed to the second-order nonpolar Raman processes, while that at 385 cm\(^{-1}\) corresponds to A1 transverse optical (TO) mode. \(^{26}\) The E1 (LO) phonon mode can be observed at 583 cm\(^{-1}\) when the c-axis of wurtzite ZnO is perpendicular to the sample surface. \(^{27}\) However, the 583 and 275 cm\(^{-1}\) peaks can be attributed to the electric field induced Raman modes as were observed \(^{28}\) previously.

In conclusion, a self-assembly technique was developed for the growth of densely packed and aligned ZnO nanorods arrays in a hydrothermal process. Well-aligned bilayers of ZnO nanorod arrays were synthesized through the formation of a thin layer of hydrotalcitelike zincowoodwardite. The zincowoodwardite plates provide an oriented growth of self-assembled densely packed and aligned ZnO nanorod arrays. This process provides a simple and reproducible fabrication method for the growth of well-aligned ZnO nanorod arrays, which could be of use in the future for the fabrication of photonic devices.
